### Doubt For Mind Control Problem 1290A :->

In the editorial it is mentioned that iterate over  $y$ . But why ?

Say my  $k = 3$  and  $m = 6$  for some  $n$  then say  $i$  force 1 guy to take first element and rest 2 to take last. Now the three people  $i$  have no control over can choose first element or not.

i.e  $i$  cannot guarantee that the next three elements (after the first one is chosen by the guy  $i$  forced) will be my element all the time. but  $i$  can say for sure is that:

the element at fourth index i.e after 3 elements can be my answer. This will of course be compared with the number obtained from the end.

so basically for each person  $i$  force to pick first element say  $i$  and  $y$  ppl  $i$  cannot force. The only element  $i$  can pick is  $(i + y + 1)$  from the start. We will get one answer from last as well.

So should  $i$  just iterate over  $i$  from 0 to  $k$ .

calculate the expected number from first and last. Take their minimum

compare globalmaximum with minimum obtained

print globalmaximum

### Plz Help

← Rev. 2

▲ 0 ▼

I'm not so clear about your doubt, so here let me try to explain one insight without  $y$  ... Observe the array below

[2, 9, 2, 3, 8, 5]

Consider when

$$k = 0, m = 4$$

All possible final states will be like these sub-arrays:

[2, 9, 2], [9, 2, 3], [2, 3, 8], [3, 8, 5]

For every states the answer is:

For every states, the answer is:

[2], [9], [8], [5]

So you can find in the worst situation, the player will get 2 as his final number.

Now consider how does "k force times" affect the answer. Actually it you can force some opponents to avoid some prefix or suffix states. (you can't avoid one state in the middle, sorry I can't explain this point.)

In the case above if k=2, you force 2 opponents to take the "2" in the front and the "5" in the back.

Then all possible final states will be like these sub-arrays:

[9, 2, 3], [2, 3, 8]

For every states, the answer is:

[9], [8]

After this force, the worst answer gets greater, right?

The focus is to find the global maximum for every possible states' answer.

Hope this can help you understand this solution better.

Nice round anyway. lol

How can we say that we can only force some opponents to take first element? I am really confused with this question please help although your explanation was very good but this part that i mentioned is yet not clear.

→ [Reply](#)

22 hours ago, # ^ |

▲ 0 ▼

Maybe this means in some stage of the whole process, you are allowed to force

Tieway59

maybe this means in some stage of the whole process, you are allow to force someone make specific choice. Like in a case when the i-th opponent take the front might make the lowest answer worse (leave some small numbers in the back), then you force him to take smaller number in the the back. Could this help?

For Div. 2 B. I consider the following:

kojak\_

Just consider all indices that contain the max value in the array. Then, for each, try to find if all the elements to its left can be made strictly decreasing. Then do similarly with the elements to its right: try to make them strictly decreasing.

If you could find one such index then the answer is true. Why do I get WA here...?

→ [Reply](#)

3 days ago, # ^ |

▲ +1 ▼

Take [1, 2, 1, 3] for example. Your algorithm will give **NO**, but a possible sharpened array generated from this could be [1, 2, 1, 0].

can some one explain how monotonic dequeue has been used in Mind Control (Div2 C / Div1 A) to solve the problem in  $O(n)$ .

→ [Reply](#)

← Rev. 2 ▲ +4 ▼

davidberard

3 days ago, # ^ |

First, calculate  $b[]$  in  $O(n)$

Then, use a min queue. Start by pushing the first  $m-k$  values into the queue, and define  $ans = 0$ .

Then perform the following steps  $k+1$  times:

← Rev. 3 ▲ +8 ▼

then perform the following steps  $K+1$  times.

1. Query  $v = \min$  in queue, and set  $ans = \max(ans, v)$
2. Add the next value of  $b$  into the queue
3. Pop a value off the front of the queue

→ [Reply](#)

← Rev. 2

▲ -21 ▼

spookywooky

3 days ago, # ^ |

This wont work. They do not take maximum, the take that ends that the max of the remaining two elements will be minimum.

Same true for your  $k$  choices, you do not take minimum, you take that what maximizes the possible result at the end.

→ [Reply](#)

▲ 0 ▼

3 days ago, # ^ |

yeah, it is wrong, just find a simple counter

but for the remaining  $M - K$  people isn't it optimal to take max? because if no one take it, i will take it in the end and the answer will better for me

→ [Reply](#)

← Rev. 2

▲ 0 ▼

mini4141

spookywooky

3 days ago, # ^ |

If you take max, the next element could be even bigger. So, what counts is what is left after you take them, not what you take.

Binary search tag D?!

→ [Reply](#)

TheSawan

3 days ago, # ^ |

▲ +8 ▼

To know how many distinct characters in range  $[L, R]$ , you can for each character do a binary search to get the first occurrence for this character greater than or equal to  $L$ , if it was smaller than  $R$  then you know that this character exists in the range .

→ [Reply](#)

ManuelLoaiza

3 days ago, # ^ |

▲ 0 ▼

Sure, you can store the position of each time a character appears on the string and find the number of times the character  $c$  appears in the range  $[l, r]$  as  $upperbound_c(r) - lowerbound_c(l)$ . That technique could be useful in other problems. You can check [this](#) code to know how to implement it.

From 1290C Sol: "Since the answer exists for  $i=n$ , there exists a such partition of the graph (into "red" and "blue" nodes). We can find it with usual dfs, and keep it for lower values of  $i$ "

Why is this coloring still optimal for  $i < n$ ? What if there is a more optimal coloring? Can someone give me a proof for why we can still use the same coloring for lower values of  $i$ ?

→ [Reply](#)

Kuroni

3 days ago, <#> [^](#) |

From the full graph to the graph representing the state  $i < n$ , we do nothing but take away edges. That means intuitively, there are less constraints to force the colorings, so the coloring still works.

why do we do `strategyAns = min(strategyAns, caseAns);` and not `max` pls help!(Div2C)

ilmaxwell

why do we do strategyAns = min(strategyAns, casAns), and not max pls help(Div2C)

→ [Reply](#)

3 days ago, # |

▲ 0 ▼

because we want to take the maximum minimum of the numbers left. The first sample case was well explained:

2 9 2 3 8 5

The first one was forced to take 5

2 9 2 3 8

The second one was forced to take 2

9 2 3 8

and One guy left, he could take 8 so we can take 9, but if he took 9 then we can take 8. so we just took the maximum minimum, and that is the least maximum number that we could take.

→ [Reply](#)

MasterMind

Mohammad\_Yasser

3 days ago, # |

▲ +66 ▼

I think I have a bit simpler implementation for Div1 C.

I use an ordinary DSU, with representing each original node  $x$  with two nodes, one that represents that  $x$  will be chosen and the other one representing that  $x$  will not be chosen, let's call them  $x_{true}$  and  $x_{false}$ .

Also, each root has a cost, which is the cost to choose that root. Initially, the cost of each root is 1 if it is a *true* node and 0 otherwise.

I also create a dummy node representing the *nochoice*. The cost of its *true* node is 0, and the cost of its *false* node is  $\infty$ .

To merge two nodes  $x$  and  $y$ , if they must take the same value, then  $join(x_{true}, y_{true})$  and  $join(x_{false}, y_{false})$ , else  $join(x_{true}, y_{false})$  and  $join(x_{false}, y_{true})$ .

To force a node to be *true* or *false*, then join it with the *nochoice* node.

The solution maintains the total cost and updates it upon merging in a similar manner to the tutorial's

The solution maintains the total cost and updates it upon merging in a similar manner to the tutorial's solution. The dummy node makes it unnecessary to care for overflows or minimize the costs with  $OO$ , since that  $OO$  will only be counted once, in the dummy node.

Regarding D,

In the problem: partition the graph having directed edges  $(i, j)$  for all  $i < j$  into edge-disjoint paths,

jtnydv25

Isn't it possible to prove using Hall's theorem that number of disjoint paths must be  $\geq$  about  $\frac{n^2}{4}$ ?

This means that 1.5 is the best possible factor for the above approach. How do you get a factor of 1.2 in randomized DFS then?

→ [Reply](#)

Ari

3 days ago, <#> [^](#) |

▲ +13 ▼

The graph is not directed. As long as we visit vertices  $i$  and  $j$  consecutively in a path in any order we will be able to remove all equalities. The only difference is which of the blocks will have elements deleted.

Is here a guy who knows a different solution of Irreducible Anagrams?

→ [Reply](#)

bayrhuu

3 days ago, # ^ |

← Rev. 2

▲ 0 ▼

I interested on it because Irreducible Anagrams has binary search, data structures, strings, two pointers problem tags .

→ [Reply](#)

Ari

3 days ago, # ^ |

← Rev. 3

▲ +12 ▼

There are quite a few other solutions to Irreducible Anagrams, differing on how the third condition is handled. I believe the one in the editorial is the most straightforward, but some other possible solutions we intended to pass include:

- Find for each left endpoint  $l$  the maximum  $x$  such that  $s[l, x]$  contains at most two different characters. After preprocessing this allows us to answer queries in  $O(1)$ . This can be done in  $O(n)$  using a somewhat straight forward two pointers algorithm, for a final complexity of  $O(n + q)$ .
- One can use any of the standard solutions for the classic "count number of distinct values in a range" problem, such as Mo's Algorithm in  $O(n\sqrt{q})$ , or Sorting + Fenwick Tree in  $O(q\log(n))$ .
- Some other silly solutions also passed, such as using segment trees instead of prefix sums to find whether a substring contains a certain character, which results in  $O(26\log n)$  per query. This is a rather strange thing to do, but some people did actually pass with solutions like this `^( ^ )_`.

I'm sure there's many other solutions that could get accepted in this problem, as constraints were low enough to allow basically everything that isn't straight up quadratic to pass.

I don't fully understand how this is harder, but let  $dp[i][j][k]$  be the answer for the subarray from  $i$  to  $j$  with  $k$  people for you to manipulate. Then  $dp[i][j][k] = \max(dp[i+1][j][k-1], dp[i][j-1][k-1])$ . When  $k = 0$ , suppose there are  $p$  people left to pick who you cannot manipulate. Then you know that they will leave some contiguous subarray of length  $(j - i + 1 - p)$ . You can iterate over all subarrays of such length and pick the minimum of the maximum of all subarrays.

I did exactly this except instead of picking the min of max of all subarrays, i picked the min of max of all (first element/last element) of subarrays. [70060565](#)

I tried to understand the statement of Div1E (Cartesian Tree), but failed. If someone understood and can clarify one thing in construction of the tree, i will be very grateful.

In the very first example, given the sequence 4, 2, 7, 3, 5, 6, 1. According to algorithm, we should take maximum, 7 in this case, so position  $x = 3$  (is it correct?). Then we construct trees for [4, 2] (left tree) and [3, 5, 6, 1] (right tree) (again, any missunderstand?). Then, due to step 5, left and right constructed trees become left and right subtrees and the root is temporary removed number. And it maximum, 7 in this case. But in example the resulting tree has root that is not 7 and 1 and 2 in the same subtree, while they were in different parts after breaking the sequence.

Where am I wrong?

P. S. I see that it is ordered as BST, and what i do is a mess. That's why i ask for some help.

The announcement for problem E says: "In the notes to samples, the nodes in the tree are labeled by indices, while the tree in the explanation is labeled by value. Sorry for the inconvenience caused. The problem doesn't change."

That's why the root of sample tree isn't "7" It labeled "3" because 7 is third element of the array (x

that's why the root of sample tree isn't 7. It labeled 0 because 7 is third element of the array ( $n = 3$ ). Also 1 and 2 are in the same subtree due to they're indices of 4 and 2 ( $a[1] = 4$  and  $a[2] = 2$ ).

Div.2 B. What is test case 2: 109th line? It seems I'm wrong with my solution, but I can't hack myself. I prepare pyramid-like triangle of "minimal possible values", and then check if all values of an array are higher (70047658).

UPD. Solved. My "pyramide" should be sharper at a top in case of even number of elements!

whats wrong in my code i check for min number at respective indices of array for  $n = 4$  it should be 0 1 2 0

Dumped

what's wrong in my code I check for min number at respective indices of array for  $n = 4$  it should be 0 1 2 0 or 0 2 1 0 and similarly for other  $n$  values (problem 2 )

Thanks. I found my mistake by looking at your examples.

Ok. How do you expand "pyramide" of higher  $N$ ? E.g.  $n == 6$ .

Thanks for the problems, I really enjoyed them. Here's an alternate solution for C.

We will find the answer for each  $i$  by iterating from 1 to  $n$ . For each set, we associate a cost of picking that set. Initially this cost is 1 for every set.

If  $i$  is currently off, then we pick the lowest cost set that contains  $i$ . We are going to keep transforming the sets and costs so that doing this produces the correct answer.

If  $i$  is off, then in this and all future iterations exactly one of the sets that contains  $i$  should be selected. If there is only one set containing  $i$ , we remove it. If there are two, say  $S$  and  $T$  where  $S$  was selected in the current iteration, then we want to have the ability to unselect  $S$  and select  $T$  instead in later iterations. The set of positions that get flipped by doing this is  $U = S \text{ xor } T$  and the cost of doing this is  $\text{cost}(T) - \text{cost}(S)$ . So we can enforce this by removing  $S$  and  $T$  and adding this new set  $U$  with this cost. (this is kind of similar to residual edges in Ford-Fulkerson; here  $U$  is a residual set)

If position  $i$  is already on, then if it is contained in exactly one set, this set should never be picked hereafter, so just remove it. If it is contained in two sets  $S$  and  $T$ , then in all future iterations either they should both be picked or neither. We can accomplish this by removing  $S$  and  $T$  and adding  $U = S \text{ xor } T$  with cost  $\text{cost}(S) + \text{cost}(T)$ .

▲ 0 ▼

Because the array wont be strictly increasing if the values of array are less than the sequence 0,1,2,3,...,n that is similar to array indexes.

I have a doubt in Div1A/Div2C: Why should I select the control the **first**  $k$  persons in the queue and not in

mshiladityam

I have a doubt in DIV 2 C. Why should I select the control the first  $k$  persons in the queue, and not in some other order: like why not first  $m - 1 - k$  can select randomly, and the last  $k$  elements should select the element I forced them too. Please help.

I\_love\_low\_

Basically, in order to know what element that  $m$ -th person picks, you need to know after  $m - 1$  persons picks the elements themselves, what the remaining subarray is. And the remaining subarray only depends on the number of persons choosing the head element (or equivalently, the amount choosing the tail element) in  $m - 1$  persons. It indicates that the order is not important, and you can pick any  $k$  persons to control.

Brute force on the persuade people by taking two-pointer one starting from 0 index(say left) and

kunal\_rai

Brute force on the persuade people by taking two pointer one starting from 0 index(say left) and one at  $n - \min(k, m - 1) - 1$  (say right), then for each pair of left and right, find the minimum element you can get by brute-forcing from left to right with the same approach of taking two-pointer one starting from left(say l) and another at  $n - m + \text{left}(\text{say } r)$ , then find minimum from  $\max(a[l], a[r], r)$  till right.

Do the same for all the values of left and right. And the maximum of all the values will be the answer.
